

Case 27

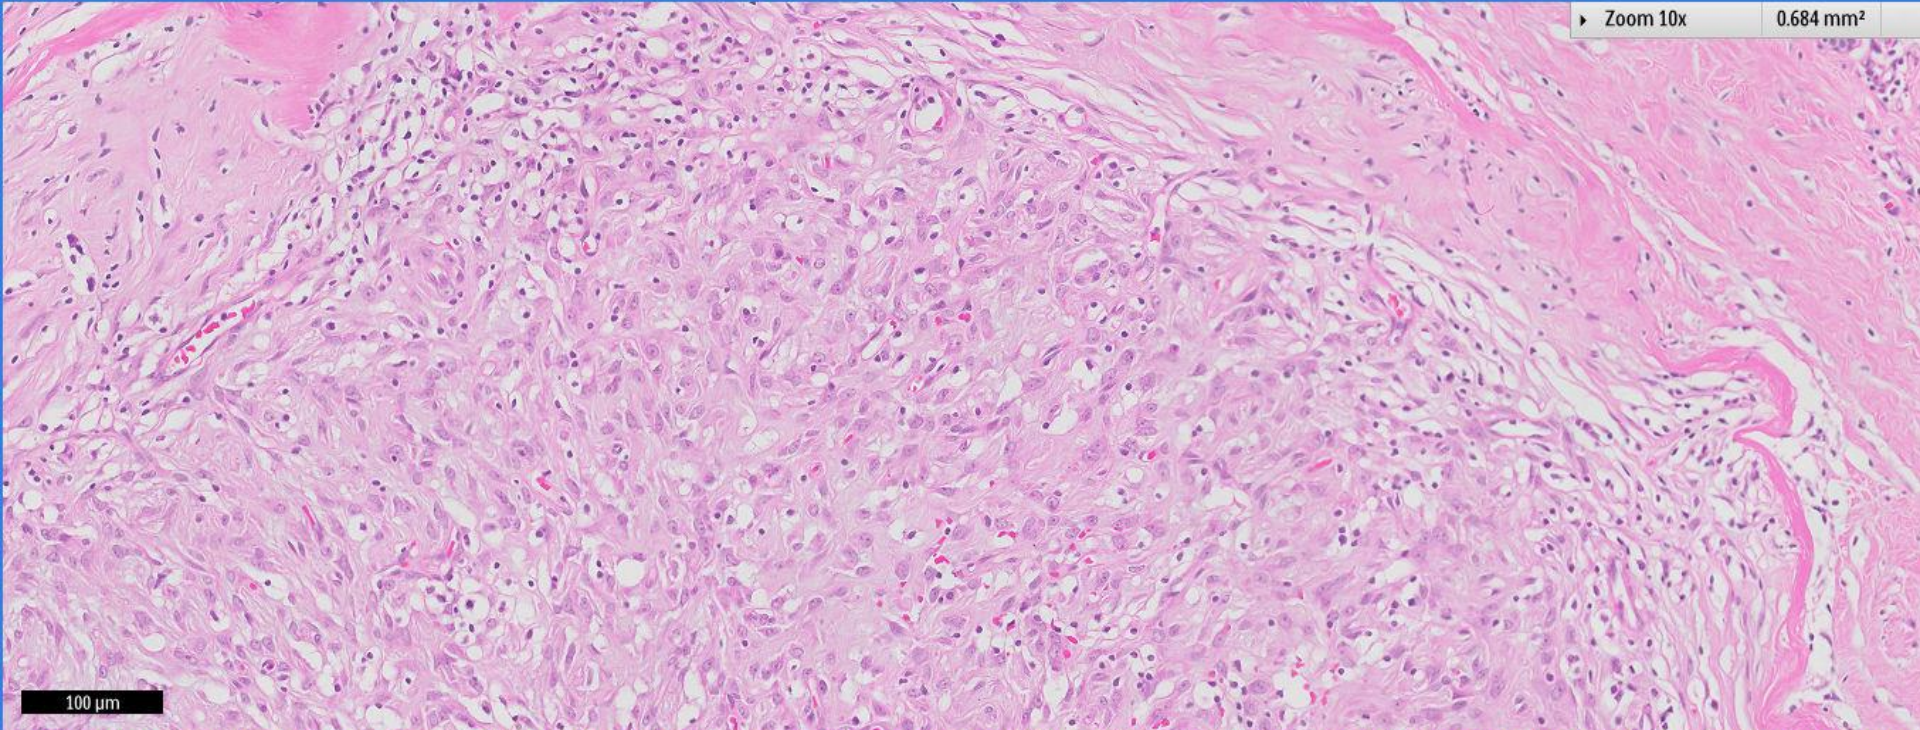

51 year old Chinese woman underwent wide excision of a left breast lump after core biopsy disclosed a malignant spindle cell tumour.

Distinguishing Features of Sarcomatous Stromal Overgrowth in Malignant Phyllodes Tumour, Spindle Cell Metaplastic Carcinoma, and Primary Breast Sarcoma

Feature	Malignant phyllodes tumour (stromal overgrowth)	Spindle cell metaplastic carcinoma	Primary breast sarcoma
Leaf-like fronds	Present (but may be hard to identify)	Absent	Absent
Peri-epithelial stromal accentuation	Present	Absent	Absent
Carcinoma (in situ and invasive)	Absent	May be present	Absent
Keratins (IHC)	Usually absent, may be focal reactivity	Present, but may be focal	Usually absent
High molecular weight keratins	Usually absent, may be focal reactivity	Present, but may be focal	Usually absent
p63, p40	Absent or present	Usually present, but may be focal	Usually absent

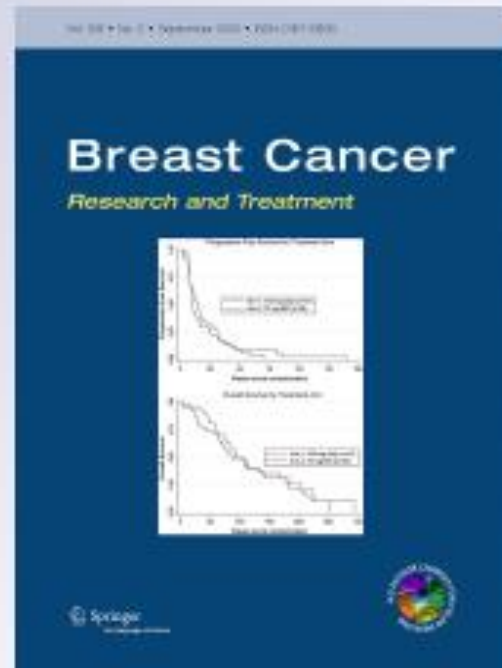

Breast sarcomas and malignant phyllodes tumours: comparison of clinicopathological features, treatment strategies, prognostic factors and outcomes

Abstract We aimed to compare the clinicopathological features, treatment strategies and clinical outcomes of breast sarcomas (BS) and malignant phyllodes tumours (MPT), and determine their prognostic factors. Cases of BS and MPT diagnosed at the Department of Pathology, Singapore General Hospital from January 1991 to December 2014 were derived from department files. Clinicopathological features, treatment strategies and survivals of patients with BS and MPT were compared. Prognostic indicators for BS and MPT were identified. BS and MPT were comparable in all except one of their clinicopathological features. A significantly higher proportion of BS patients had a history of previous breast carcinoma and thus radiation to the chest as compared to the MPT group (17.6 vs 0 %, $P = 0.018$). There was no significant difference in survival outcomes between BS and MPT. The 5-year disease-free survivals (DFS) for BS and MPT were 59.1 and 57.4 % respectively ($P = 0.816$), while the 5-year overall survivals (OS) for BS and MPT were 86.5 and 78.5 % respectively ($P = 0.792$). Combining both groups of tumours, univariate analysis showed that DFS was significantly affected by multifocality ($P = 0.019$),

histological subtype ($P = 0.014$), presence of malignant heterologous elements ($P < 0.001$) and margin status ($P = 0.023$). Margin status was the only parameter which had a significant impact on OS ($P = 0.040$). Multivariate analysis confirmed the above findings. BS and MPT are rare entities with remarkable heterogeneity. They share similar clinicopathological features and outcomes, provoking thoughts on their biological relationship and clinical significance of pathologic distinction.

PATHOLOGY

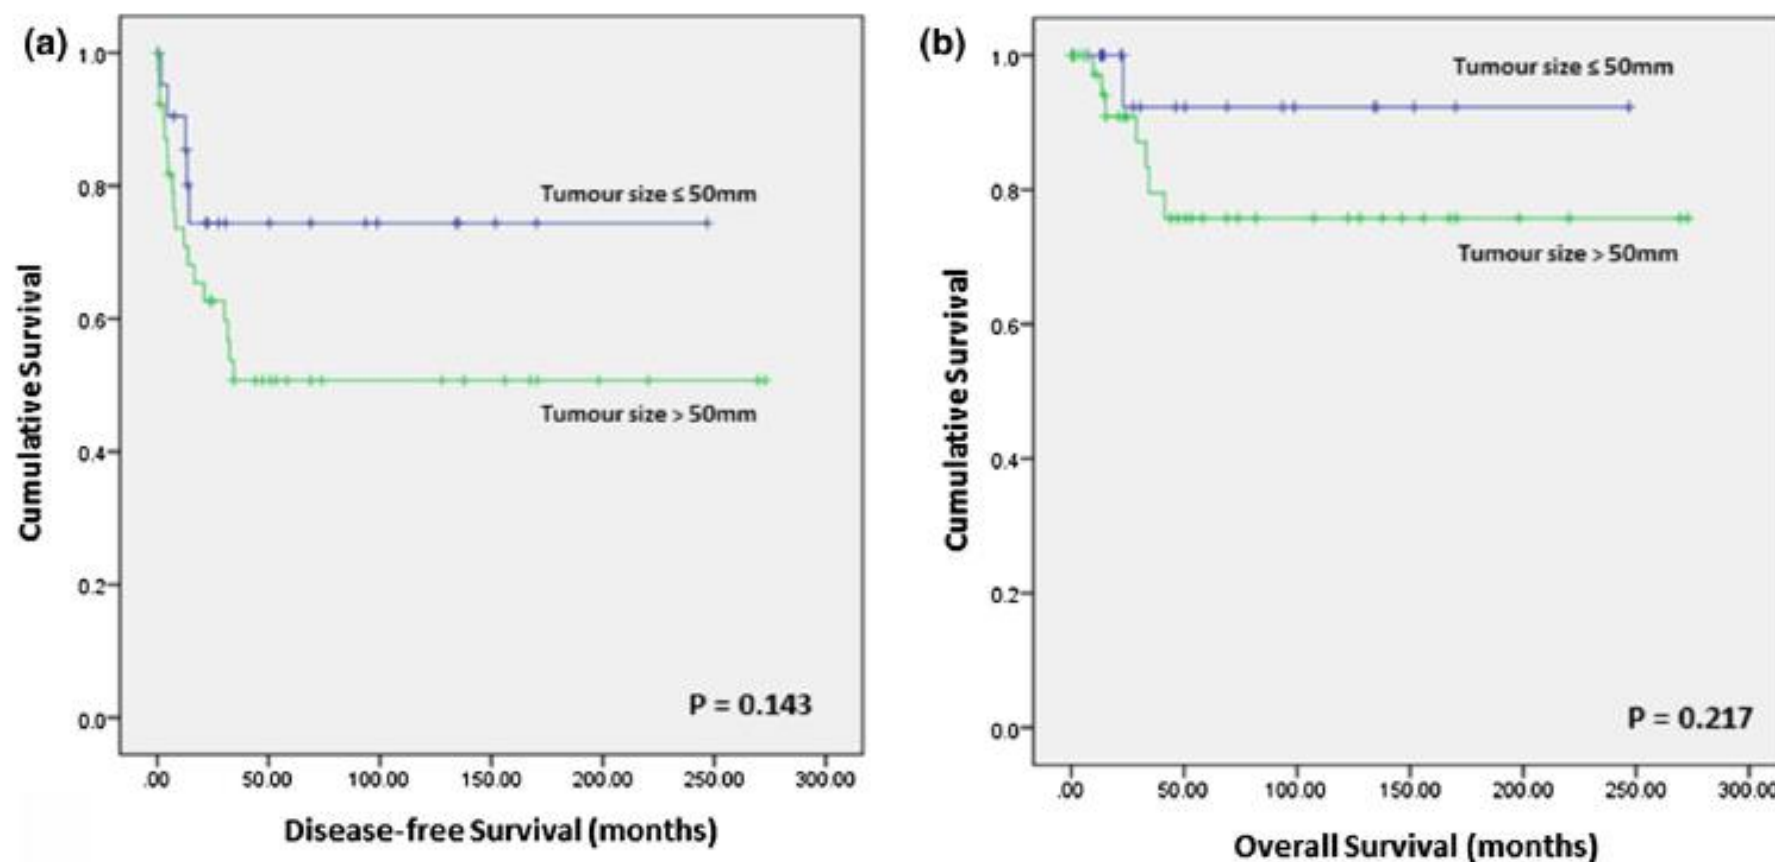

Fig. 5 Kaplan-Meier curves showing the **a** DFS and **b** OS of tumours ≤ 50 mm and tumours > 50 mm. There was a trend of improved survival in patients with tumours ≤ 50 mm as compared to those with tumours > 50 mm

Table 6 Multivariate analysis on potential prognostic factors on DFS and OS for both BS and MPT

Clinicopathological parameter	DFS			OS		
	HR	95 % CI	P value	HR	95 % CI	P value
Multifocality						
Yes	10.869	2.134–55.348	0.004*	NA	NA	0.993
No	1					
Histological subtype						
Angiosarcoma	8.979	2.168–37.183	0.002*	NA	NA	0.346
Others	1					
Malignant heterologous element						
Yes	20.515	5.366–78.431	<0.001*	NA	NA	0.313
No	1					
Margin						
Positive	5.456	1.987–14.980	0.001*	5.166	1.131–23.596	0.034*
Negative	1			1		

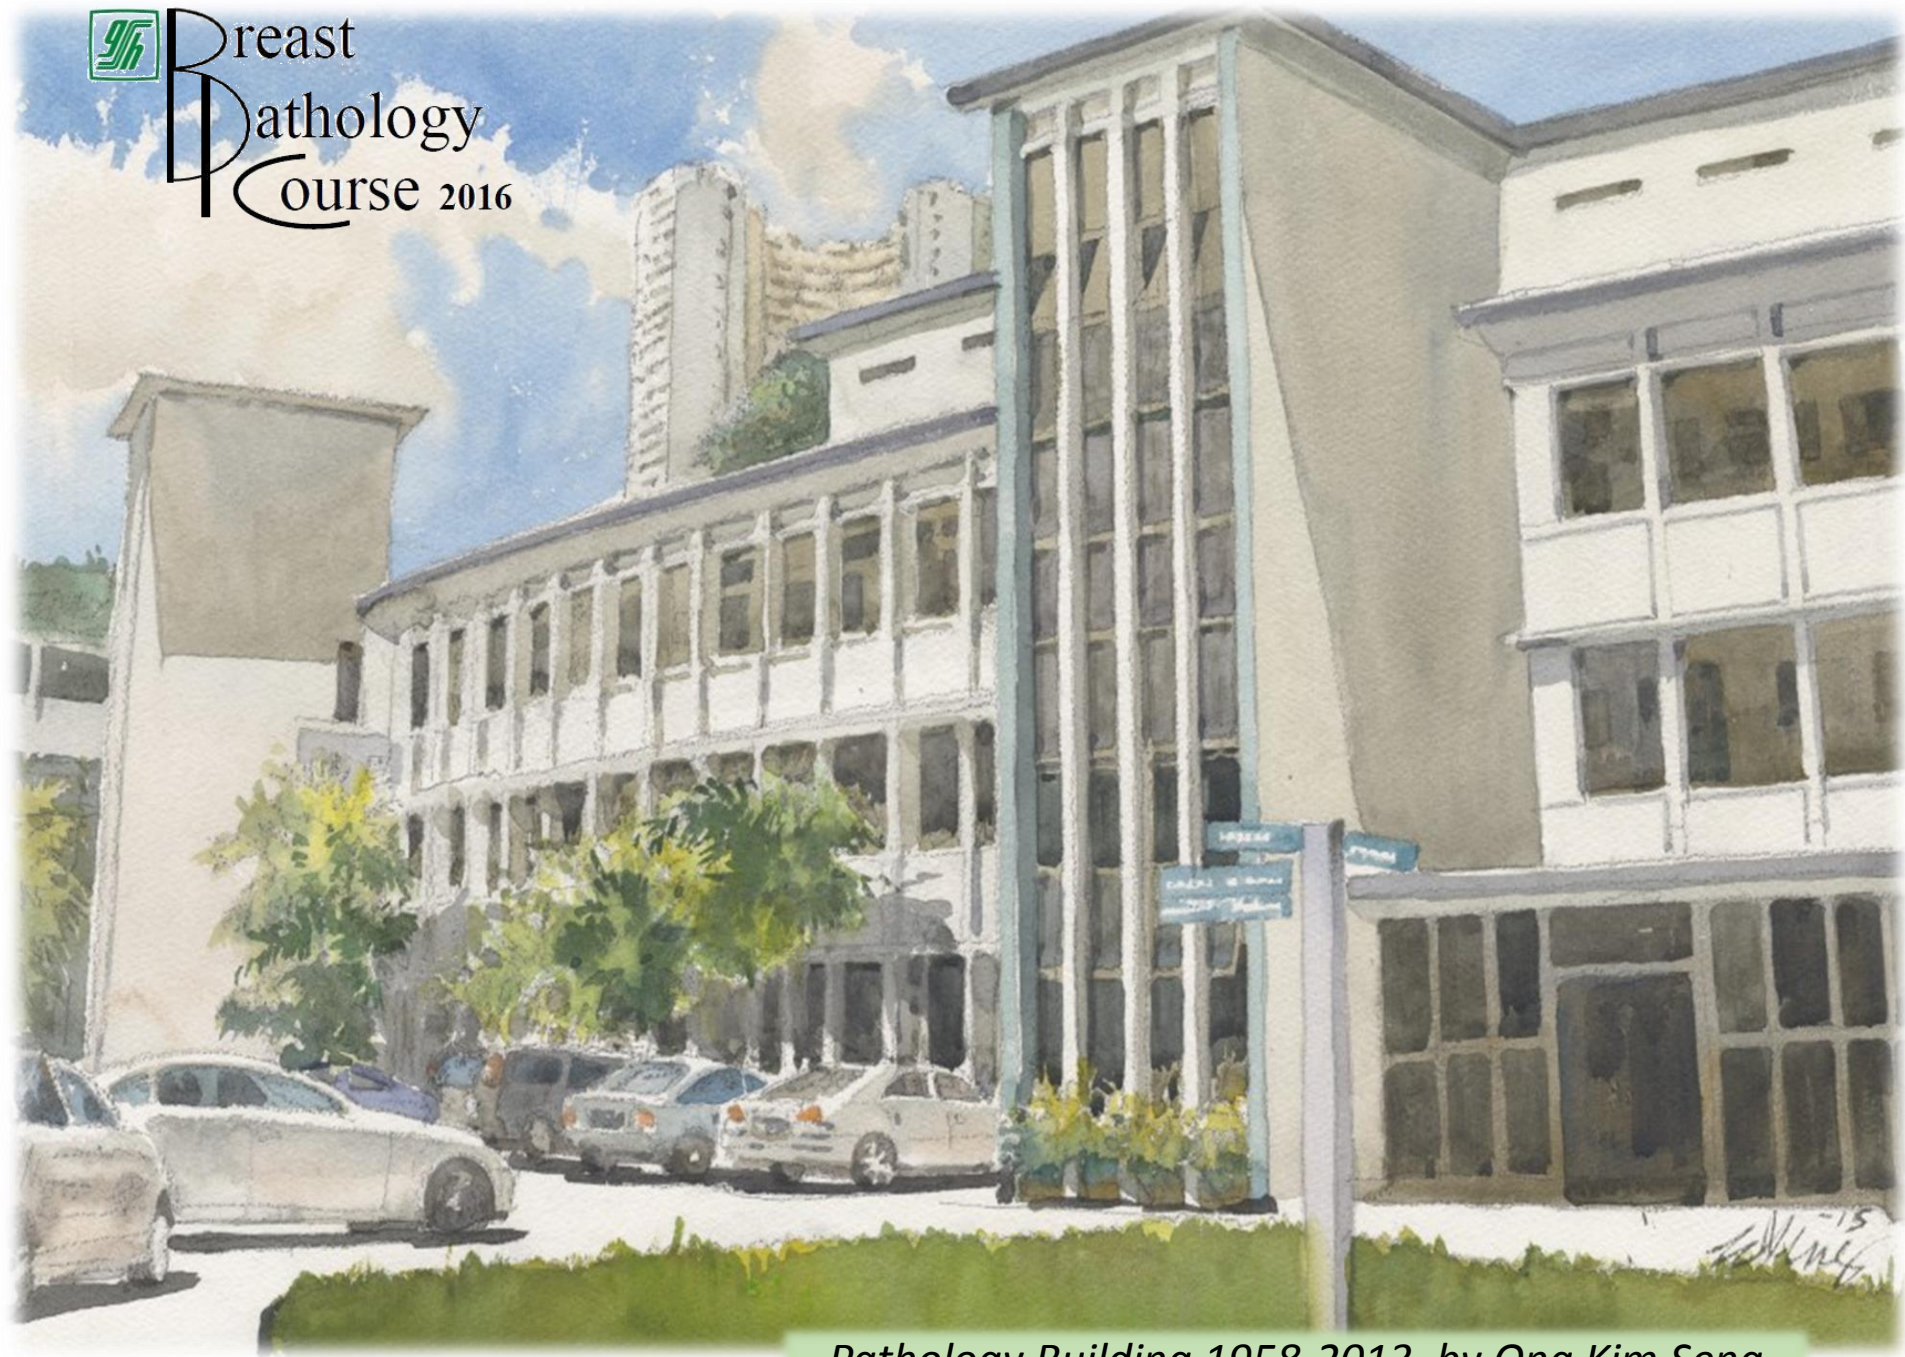

HR Hazard ratio, *CI* Confidence interval

Summary

- Malignant phyllodes tumours and breast sarcomas share similar clinicopathological features and clinical outcomes.
- Surgical resection with negative margins is the mainstay of treatment.
- Margin status is the only parameter significantly influencing DFS and OS.
