PATHOLOGY

Additional radiological information

- Ultrasound lesion appeared entirely within the breast parenchyma, with a layer of fat to the chest wall of about 4mm.
- There was concern that the ultrasound could underestimate the size of the lesion, and the radiologist recommended further evaluation with MRI.
- No information if the MRI was performed.

CD31

CD34

F8

Ki67

Diagnosis

Well differentiated vasoformative lesion,
consistent with a well differentiated
angiosarcoma, 13mm.

Ki67 proliferation about 15%.

Angiosarcoma of the breast

- **Primary (de novo)**, arising in breast parenchyma.
- **Secondary**, develops in the skin, chest wall or breast parenchyma subsequent to surgery and postoperative radiation for breast cancer.
 - Notably increasing frequency since the late 1980s, reflecting the trend for breast-conserving surgery with more frequent use of radiation.
 - Angiosarcoma is the commonest radiation induced sarcoma in the breast.
- Vary in size from 1 to 25cm (average, 5 cm) and often have a spongy haemorrhagic appearance with ill-defined borders.
